Cifar10

Algorithms:

Random Forest Classifier

K-nearest neighbors

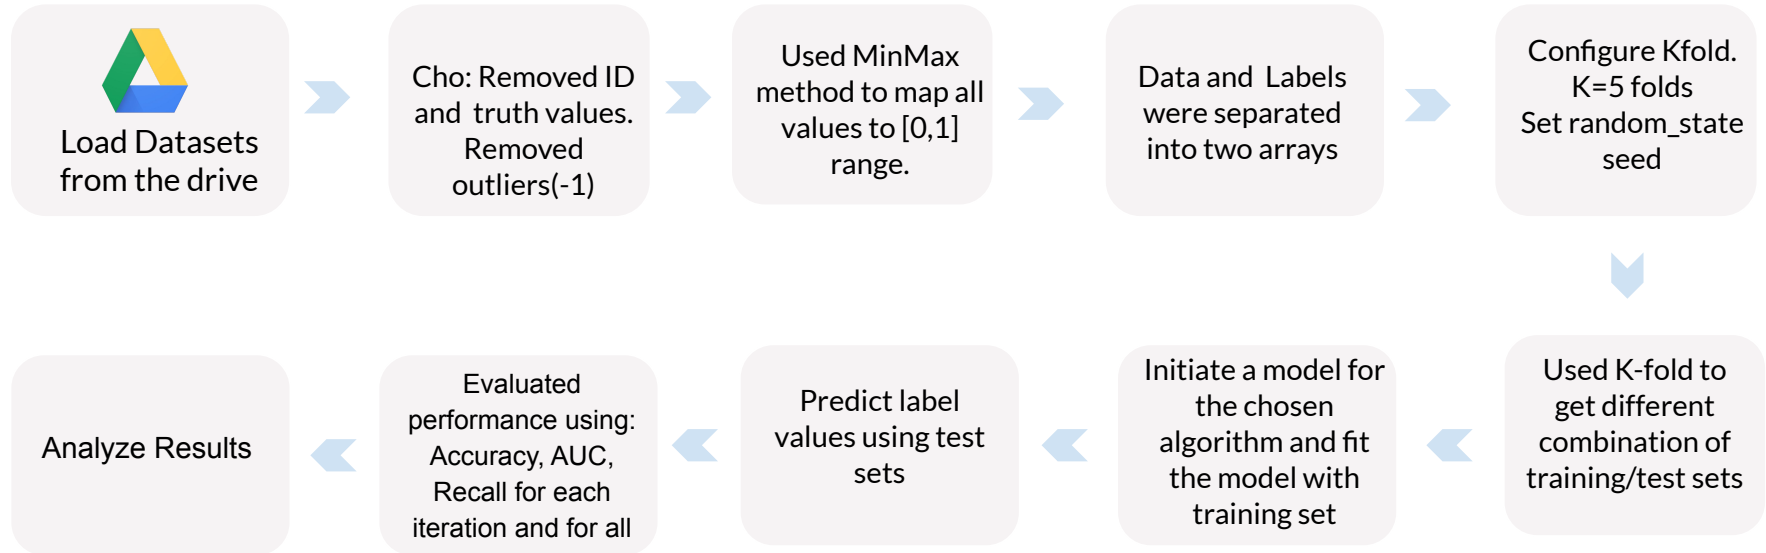

Support Vector Machine

Data Processing and Classifying

Algorithm Overview - Random Forest

How it works:

- ❖ Random forest is an ensemble, tree-based algorithm
- ❖ The RF classifier generates a set of classification trees that each classify an object and “vote” for the class of the object
 - In this implementation, each tree outputted a probabilistic prediction, so not just a vote for one class, but different weights that could contribute to several classes
- ❖ The overall forest then considers all votes and chooses a final classification for the object
- ❖ Having several trees cuts down on variance and overfitting that can occur with just one tree
- ❖ The main parameter is **n_estimators**, which determines the number of trees in the forest
 - n_estimators = 100 was chosen with the same seed for each run
 - Choosing a higher value for n_estimators could increase accuracy, but greatly increases run time

Algorithm Overview - K-Nearest Neighbor

How it works:

- ❖ The k-nearest neighbors (KNN) algorithm is a simple, easy-to-implement supervised machine learning algorithm.
- ❖ Assumes that similar things exist in close proximity.
- ❖ Stores all available cases and classifies new cases based on a similarity measure.
 - Distance function - Euclidean distance
- ❖ A case is classified by a vote of its neighbors.
 - Majority voting vs. weighted voting

Algorithm Overview - Support Vector Machine

How it Works:

- ❖ find a hyperplane in an N-dimensional space to separate classes
- ❖ Out of all possible hyperplanes maximize the margin.
- ❖ Uses Lagrangian to solve the optimization problem
- ❖ When not linearly separable, use Kernel functions : linear, poly, rbg, sigmoid, precomputed, callable

- ❖ I used the Radial Basis Function (RBF).
 - Creates additional features to increase dimensions
 - Points that were hard to classify linearly, become easily separable in higher dimensions.

Setbacks - difficulties

- ❖ K-nearest neighbors and Support vector machine are time inefficient on large datasets
 - Cifar10 took hours to finish
 - Made it hard to test with different parameters
 - A way to go around was to test on a smaller part of Cifar
- ❖ Working with datasets
 - Datasets were fairly different (Image vs. numerical)
 - Understanding datasets, features, type, size
- ❖ Detecting Outliers/noise
 - Hard to see for cho
 - Easier for Cifar since images are easier to visualize

Comparing Results

SVM (Cho):

| | | | |
|--------------------|--------|--------|--------|
| Average | 0.7695 | 0.8417 | 0.7658 |
| Standard Deviation | 0.0510 | 0.0461 | 0.0348 |

SVM (CIFAR):

| | | | |
|--------------------|--------|---------|--------|
| Average | 0.5455 | 0.7082 | 0.5470 |
| Standard Deviation | 0.0510 | 0.04611 | 0.0349 |

KNN (Cho):

| | | | |
|--------------------|--------|--------|--------|
| Average | 0.7383 | 0.8282 | 0.7248 |
| Standard deviation | 0.0213 | 0.0122 | 0.0198 |

KNN (CIFAR):

| | | | |
|--------------------|--------|--------|--------|
| Average | 0.3388 | 0.6327 | 0.3389 |
| Standard deviation | 0.0043 | 0.0016 | 0.0027 |

Random Forest (Cho):

| | | | |
|--------------------|--------|--------|--------|
| Average | 0.7305 | 0.8246 | 0.7193 |
| Standard Deviation | 0.0295 | 0.0222 | 0.0378 |

Random Forest (CIFAR):

| | | | |
|--------------------|--------|--------|---------|
| Average | 0.4641 | 0.7023 | 0.46412 |
| Standard Deviation | 0.0046 | 0.0025 | 0.0045 |

Observations and takeaways

Observations:

- Large vs. small datasets with different algorithms
- Different types of data perform differently
 - Image vs. numerical values
 - Question of quality of data

Takeaways:

- Parameter tuning is difficult and time consuming
 - Many parameters to consider
- Different algorithms work better for certain tasks
